

Strategic Allocation Programme

Buy on the market → burn what you bought → receive 1.25× over 12 months

Capital that buys the token instead of selling it — at effectively zero cost to the network

Computer briefing · pilot proposal · v5

15 September 2026 · market data verified, post-halving (Epoch 227)

The problem: we need capital, and every normal route sells tokens

~6 months

CCF runway

Balance 984.7B QUBIC (~\$387k at today's price). Inflow \$100.5k per quarter against ~\$288k of approved spend. The halving cut treasury income by 65%.

\$0.73M

daily traded volume

A \$55.9M market cap on tier-2 venues. Any treasury sale of size lands on a thin order book — and everyone sees the protocol selling.

0

tokens we can sell cleanly

A discounted treasury sale adds supply, drains the CCF, and tells the market we are selling to survive. The worst option on the table.

The question this deck answers: how do we raise outside capital and strengthen the holder base without selling a single token?

The idea in one line

Investors buy QUBIC on the open market, burn what they bought, and receive **1.25 tokens for every 1 burned** — released in small batches over twelve months.

1 They buy

~\$500k executed by our market maker through the investor's own account. Their money never touches Qubic.

2 They burn

The tokens they bought are destroyed at the burn address. On-chain, irreversible, verifiable by anyone.

3 We repay in emission

1.25× the burn, from emission that would have been burned anyway — drip-released so there is never a block to sell.

Every ticket hits the price twice: ~\$500k of real market buying, then an immediate burn — demand up and float down before a single token is issued back. Qubic sells nothing, holds no investor money; 0.25 per token burned is our entire cost.

How it works

The allocation is triggered by the burn PLUS the market-maker attestation — the premium is only ever paid for real, fresh buying.

Two gates: no contract → no ratio (an uncontracted burn earns nothing) · no attestation → no ratio (burning an old bag earns nothing)

The math of one ticket

Price used throughout: \$0.000000393 (verified 15 Sep 2026). The deal itself is denominated in tokens — no price is ever negotiated.

Step	QUBIC	How it is calculated
Investor buys & burns	1.2726 T	$\$500,000 \div \0.000000393
Investor receives back	1.5907 T	$1.2726T \times 1.25$ (= burn $\div$ 0.80 — a 20% effective discount)
Qubic net new supply	0.3181 T	$1.5907T - 1.2726T$ (= 0.25 $\times$ the burn)
Each release batch	122.4 B	$1.5907T \div 13$ — fixed in tokens ($\approx$ \$48k at ref. price)

1 → 1.25

the ratio the investor gets

0.25

our cost per token burned

~53% p.a.

investor return if price never moves

Why the price disappears: the investor buys with their own money and settles in tokens. Execute badly → burn fewer tokens → receive proportionally less. Their execution, their consequence. Nothing to negotiate, nothing to manipulate.

The release mechanism

Nothing is unlocked up front. The full 1.25x accrues to the programme multisig and is earned batch by batch — by compliance, not by time alone.

12 months

52 epochs per ticket, start to final batch

4 epochs

the cliff: burn first, first release one month later

13 × 122.4B

equal linear batches, one every 4 epochs

Every batch is conditional

A batch is released only if the no-hedging covenant stands and the C1 commitments are current at that date. Compliance is checked before each release, thirteen times — not once at signing.

Breach ends everything forward

On breach, every unreleased batch is forfeited. Forfeited tokens are never minted, so a breach makes the programme cheaper and the supply tighter — the penalty enforces itself.

Why equal batches, why token-denominated

Each batch is $\approx 0.09\%$ of circulating supply — fixed in tokens whatever the price does ($\approx \$48k$ at the reference price; dollar value scales with price). Shortening the schedule is the one negotiating lever, and it costs us nothing.

The pilot: two tickets

2

tickets, max 2 per investor

2.55T

bought & burned (1.79%)

3.18T

issued back (2.24%)

0.64T

net new supply (0.45%)

0

treasury tokens spent to run it

Burn first, release in small steps: float below today until ~month 11

What the chart says

Burning is front-loaded: float drops ~2.3T inside two months.

Releases are back-loaded: 13 small batches — float does not return to today's level until ~month 11.

A treasury sale would move up from day one.

The comparison that decides it

Pilot scale: 3.18T issued in every scenario that raises capital. What differs is what we get for it.

	Do nothing	Sell treasury at 20% off	This programme
New supply	0	+3.18T	+3.18T
Supply destroyed	0	0	−2.55T
Net supply change	0	+3.18T	+0.64T
Verified market buying	\$0	\$0	~\$1,000,000
Treasury tokens spent	None	3.18T	None
Cash held by Qubic	\$0	\$1,000,000	\$0 — investors keep custody

One fifth of the supply impact of a treasury sale, zero treasury spend, and the whole ticket becomes open-market demand. Against doing nothing it costs 0.64T — published, capped, and the entire price.

Where the tokens come from

From the burn tranche of weekly emission — never the treasury, never miner rewards.

Weekly emission: 1,000B	Share	During the pilot quarter
Burned	775B (77.5%)	530B still burned + 245B to the programme
Miners	181.6B (18.2%)	Untouched
QEarn	25.4B (2.5%)	Untouched
CCF (treasury)	18.0B (1.8%)	Untouched

Why one or two allocations is impossible

One ticket alone = 2.05 epochs of the entire weekly burn. The pilot needs 4.10 epochs' worth.

Recommended: 13 epochs (one quarter) — a 32% draw, then the tranche expires automatically.

Protocol change required. Redirecting emission is the same class of decision as a halving — only the Computer quorum can approve it. This proposal goes to the quorum directly.

If the quorum wants the CCF funded — the options

The recommendation stays 100% burn for the pilot. But the dial exists, and the quorum should see its price.

Where each ticket's tokens go — burn share vs CCF share

CCF receives · supply cost

B0 · 100% burn	100% burned	\$0 cost 0.25x
B1 · 90% burn / 10% to CCF	90% burned 10%	\$50k / ticket cost 0.39x
B2 · 80% burn / 20% to CCF	80% burned 20%	\$100k / ticket cost 0.56x
B3 · 70% burn / 30% to CCF	70% burned 30%	\$150k / ticket cost 0.79x
B4 · 50% burn / 50% to CCF	50% burned 50%	\$250k / ticket cost 1.50x

How to read it

The investor still buys the full ticket on the market. The dial only changes where the bought tokens go: burned, or delivered to the CCF as treasury reserve.

Every 10% routed to the CCF gives the treasury ~\$50k per ticket in QUBIC — and raises our net supply cost, because those tokens are no longer destroyed.

At 50/50 the cost hits 1.50x — we create more supply than we destroy. That is the line never to cross.

The cash variant is the honest one. Tokens do not pay lawyers or auditors. If the treasury needs funding, take the CCF share as a USDT fee instead (90% market-buy + 10% cash = \$50k hard currency per ticket, same 0.39x cost, ratio lifted to ~1.39 so the investor stays whole).

Recommendation

B0 for the pilot. Revisit the dial at full scale, when there are real bills to pay.

The guardrails

1 Contract gate

Only a signed investor earns the ratio. Anyone else who burns has simply donated to the burn.

2 Attestation gate

The 1.25× is paid only for tokens our market maker attests were bought through the investor's account during the window. Burning an old bag earns nothing.

3 No-hedging covenant

No shorts, perpetuals or equivalents for the full release period, backed by a sworn declaration. Breach forfeits every unreleased batch.

4 Qubic holds the tokens

Releases come from the programme multisig — 3-of-5 signatories; the custody structure is finalised and published before launch. On breach, releases simply stop.

5 Releases too small to dump

Each batch is ~122.4B — $\approx 0.09\%$ of circulating supply, fixed in tokens whatever the price. There is never a block on the market.

6 Published before launch

Full terms and addresses public before any investor is approached — tier-1 listing diligence will find an undisclosed allocation, and that discovery is near-disqualifying.

Why an investor signs

And what we require from them beyond capital.

What they get

20% discount without an OTC desk — 25% more tokens than their money bought

~53% annualised at a flat price, over the twelve-month release

No dead period — first batch four weeks after attestation, then every four epochs

Full custody — their funds never touch Qubic; the deal is visible on-chain end to end

Negotiating lever: *if demand is weak, shorten the schedule (costs nothing) — never deepen the discount (raises our cost 70%).*

What we require

C1 — mandatory for every ticket

Quarterly co-published content, named public support, ecosystem amplification across their channels. No commitment, no allocation.

C2 — earns +5% bonus

A delivered co-marketing campaign with measurable reach, or a project-partnership introduction that reaches agreement stage. Paid only on verified delivery.

C3 — earns +10% bonus

A confirmed tier-1 exchange listing, or a signed project partnership live in the ecosystem. Worth more than the whole pilot — a listing lifts the volume ceiling that caps this programme.

The decision — one vote, three design options

THE COMPUTER QUORUM DECIDES

One vote: the temporary emission tranche ($245B \times 13$ epochs), with the three design options below settled in the published proposal. No investor is promised anything until it passes.

Decision	Recommendation	Why
A — Funding speed	13 epochs (one quarter)	32% of the burn, then automatic expiry. Faster is arithmetically impossible; slower drags the draw across a year.
B — Treasury share	None for the pilot — 100% burn	Cleanest story, cheapest supply ($0.25\times$). A cash-fee variant exists for full scale if the quorum wants it.
C — Investor obligations	C1 mandatory · C2/C3 earned	Marketing and project partnerships, never a moving purchase ratio. Bonuses paid on verified delivery from a separate pool, forfeited if missed.

If no investor signs, the tranche simply expires: no tokens issued, nothing lost. Legal and admin setup costs sit outside this decision — requested via a separate proposal if and when they arise.

What is required from each body

The programme team proposes, the core devs build, the quorum decides — in that order. Every item below is in the critical path.

PROGRAMME TEAM

proposes and operates

Publish the full proposal

Design options (A/B/C), terms, schedule and all addresses public in the qubic/proposal repo before the vote.

Prepare the legal template

Agreement + attestation format; any costs requested via a separate proposal.

Operate the programme

3-of-5 multisig signatories appointed and published; releases executed on schedule, on-chain.

Report publicly

Months 6 and 12: pass/fail against the four pilot tests, published for the quorum.

CORE DEV TEAM

scopes and ships

Emission-tranche change

245B/epoch redirected from the burn tranche for 13 epochs, hard auto-expiry in code.

Batch-release routine

13 equal releases per ticket from the multisig, one every 4 epochs after the cliff.

Verification tooling

Burn-address monitor + attestation record format, publicly checkable end to end.

Scope first, then estimate

Engineering sizing lands before the Computer proposal is submitted — no blind vote.

COMPUTOR QUORUM

decides one thing

One vote, narrowly framed

Temporarily redirect 245B/epoch of the burn tranche for 13 epochs. That is the whole ask.

Everything else untouched

Cap unchanged · miner rewards untouched · QEarn and CCF untouched · auto-expiry.

Sequencing protects everyone

No investor is approached, promised or signed until the vote passes.

Veto real — before signing

Decline = zero-cost end. Once a ticket is signed, its schedule is honored from accrued tokens; changes touch future tickets only.

The pilot passes if all four hold

1 Quorum approves the emission tranche

2 A real investor signs the full package — attestation, no-hedge, C1 — undiluted

3 Buy → burn → attest → release completes end to end, on schedule

4 The marketing and partnership commitments are delivered in the first two quarters

Fail any one and the full programme does not proceed.

Next steps

- 1 Proposal published in full with design options (A: 13 epochs · B: 100% burn · C: C1 mandatory)
- 2 Engineering scopes the tranche code change and batch-release routine
- 3 Counsel drafts the agreement template (costs via separate proposal)
- 4 Computer proposal submitted; programme published in full
- 5 Two tickets from the Tier-1 investor list — public review at months 6 and 12

Key figures · 15 Sep 2026

Price \$0.000000393 · mcap \$55.9M
Circulating 142.21T · vol \$0.73M/day
Emission 1T/epoch · burn 775B (77.5%)
CCF 984.7B (~\$387k) · runway ~6 months
Next halving Epoch 279 (~Aug 2027)
