

## Strategic Allocation Programme

Buy on the market → burn what you bought → receive  $1.10\times$ – $1.25\times$  by ticket size

*Capital that buys the token instead of selling it — at effectively zero cost to the network*

Computer briefing · pilot proposal · v7

October 2026 · market data ref. 15 Sep 2026, post-halving (Epoch 227)

# The problem: we need capital, and every normal route sells tokens

---

**~6 months**

**CCF runway**

Balance 984.7B QUBIC (~\$387k at today's price). Inflow \$100.5k per quarter against ~\$288k of approved spend. The halving cut treasury income by 65%.

---

**\$0.73M**

**daily traded volume**

A \$55.9M market cap on tier-2 venues. Any treasury sale of size lands on a thin order book — and everyone sees the protocol selling.

---

**0**

**tokens we can sell cleanly**

A discounted treasury sale adds supply, drains the CCF, and tells the market we are selling to survive. The worst option on the table.

**The question this deck answers:** how do we raise outside capital and strengthen the holder base without selling a single token?

# The idea in one line

Investors buy QUBIC on the open market, burn what they bought, and receive a tiered multiple — 1.10× to 1.25× by ticket size — released in small batches over six to twelve months.

## 1 They buy

\$100k-\$500k executed by our market maker through the investor's own account. Their money never touches Qubic.

## 2 They burn

The tokens they bought are destroyed at the burn address. On-chain, irreversible, verifiable by anyone.

## 3 We repay in emission

The tier multiple, from emission that would have been burned anyway — drip-released, so there is never a block to sell.

**Every ticket hits the price twice: real market buying, then an immediate burn — demand up and float down before a single token is issued back. Qubic sells nothing, holds no investor money; 0.10-0.25 per token burned, by tier, is our entire cost.**

# How it works

The allocation is triggered by the burn PLUS the market-maker attestation — the premium is only ever paid for real, fresh buying.

## INVESTORS PILOT — BUY · BURN · TIERED RELEASE

### 1 · CONTRACT

Attestation req.  
No-hedge covenant  
Ecosystem commitments

### 2 · BUY

\$100k-\$500k ticket  
Qubic market maker  
investor's own account

### 3 · BURN

100% destroyed at  
burn address  
immediately · on-chain

### 4 · RELEASE

Tier multiple accrues  
13 equal batches max  
every batch conditional

*No contract → no ratio · No attestation → no ratio · Breach → all unreleased batches burned*

**Two gates:** no contract → no ratio (an uncontracted burn earns nothing) · no attestation → no ratio (burning an old bag earns nothing)

# The math of a ticket — three tiers

Price used throughout: \$0.000000393 (verified 15 Sep 2026). The deal itself is denominated in tokens — no price is ever negotiated.

| Step — Tier C example  | QUBIC    | How it is calculated                                                  |
|------------------------|----------|-----------------------------------------------------------------------|
| Investor buys & burns  | 1.2726 T | $\$500,000 \div \$0.000000393$                                        |
| Investor receives back | 1.5907 T | $1.2726T \times 1.25$ (= burn $\div$ 0.80 — a 20% effective discount) |
| Qubic net new supply   | 0.3181 T | $1.5907T - 1.2726T$ (= 0.25 $\times$ the burn)                        |
| Each release batch     | 122.4 B  | $1.5907T \div 13$ — fixed in tokens ( $\approx$ \$48k at ref. price)  |

**1.10 / 1.15 / 1.25**

the ratio by ticket — \$100k / \$250k / \$500k

**0.10-0.25**

our cost per token burned, by tier

**7 / 10 / 13**

batches by tier — money back in  $\sim 6$  /  $\sim 9$  / 12 months

**Why the price disappears: the investor buys with their own money and settles in tokens. Execute badly  $\rightarrow$  burn fewer tokens  $\rightarrow$  receive proportionally less. The rate attaches to the ticket, so splitting into smaller tickets only earns a lower rate — fragmentation penalises itself.**

# The release mechanism

Nothing is unlocked up front. The full tier multiple accrues to the programme multisig and is earned batch by batch — by compliance, not by time alone.

Release ladders by tier — 13 batches maximum, fixed in tokens

## 6-12 months

28 / 40 / 52 epochs per ticket by tier, start to final batch

## 4 epochs

the cliff: burn first, first release one month later

## 7 / 10 / 13

equal batches by tier, one every 4 epochs

### Every batch is conditional

A batch is released only if the no-hedging covenant stands and the C1 commitments are current at that date. Compliance is checked before each release, at every batch — not once at signing.

### Breach ends everything forward

On breach, every unreleased batch is forfeited. Forfeited tokens are never minted, so a breach makes the programme cheaper and the supply tighter — the penalty enforces itself.

### Why equal batches, why token-denominated

Each batch is 0.03%-0.09% of circulating by tier — fixed in tokens whatever the price does (~\$15.7k-\$48.1k at the reference price). The Tier C final batch carries the verified partnership bonus (+63.6B → ~185.9B). Shortening the schedule is the one negotiating lever, and it costs us nothing.

# The pilot: \$1M cap, tiered tickets

**\$1M**

cap · max 6 tickets · 2 per investor — 2nd earned by clean execution of the 1st

**2.55T**

bought & burned (1.79%)

**3.18T**

issued back (2.24%)

**0.64T**

net new supply, base (max 0.76T · 0.54% with bonus; as low as 0.38T at lower tiers)

**0**

treasury tokens spent to run it

Float impact — burn first, releases later; lower tiers only shrink this curve

## What the chart says

**Burning is front-loaded:** float drops ~2.3T inside two months.

**Releases are back-loaded:** 13 small batches — float does not return to today's level until ~month 11.

**A treasury sale would move up from day one.**

# The comparison that decides it

Pilot scale: up to 3.18T issued at the worst-case composition — lower tiers cost strictly less. What differs is what we get for it.

|                          | Do nothing | Sell treasury at 20% off | This programme               |
|--------------------------|------------|--------------------------|------------------------------|
| New supply               | 0          | +3.18T                   | +3.18T                       |
| Supply destroyed         | 0          | 0                        | −2.55T                       |
| <b>Net supply change</b> | <b>0</b>   | <b>+3.18T</b>            | <b>+0.64T</b>                |
| Verified market buying   | \$0        | \$0                      | ~\$1,000,000                 |
| Treasury tokens spent    | None       | 3.18T                    | None                         |
| Cash held by Qubic       | \$0        | \$1,000,000              | \$0 — investors keep custody |

**One fifth of the supply impact of a treasury sale, zero treasury spend, and the whole ticket becomes open-market demand.** Against doing nothing it costs 0.64T — published, capped, and the entire price.

# Where the tokens come from

From the burn tranche of weekly emission — never the treasury, never miner rewards.

| Weekly emission:<br>1,000B | Share          | During the pilot quarter                           |
|----------------------------|----------------|----------------------------------------------------|
| <b>Burned</b>              | 775B (77.5%)   | 53.0% still burned + 24.5% to programme (max 245B) |
| Miners                     | 181.6B (18.2%) | <b>Untouched</b>                                   |
| QEarn                      | 25.4B (2.5%)   | <b>Untouched</b>                                   |
| CCF (treasury)             | 18.0B (1.8%)   | <b>Untouched</b>                                   |

Donation split during the window — amounts shown are maximums; the bonus is funded inside the 24.5%

## Why one or two allocations is impossible

Donations are a % of actual Computer earnings — all figures are ceilings. Window: 15 epochs (14 nominal + 1 buffer), sized to the max obligation incl. the Tier C partnership bonus: 3.675T ceiling vs 3.31T max owed (~11% margin; the worst accrual week on-chain, 95.6% of ceiling, still covers).

Burn-back rule: unearned bonus reserve and all surplus are burned at close, hashes published. The multisig holds nothing after programme close.

**Two paired votes, no code changes.** Proposal A redirects 24.5 points of the burn donation; Proposal B — published simultaneously — restores 77.5% at window close. Standard donation mechanics, same class as the QEarn and halving votes.

# If the quorum wants the CCF funded — the options

The recommendation stays 100% burn for the pilot. But the dial exists, and the quorum should see its price.

## Where each ticket's tokens go — burn share vs CCF share

CCF receives · supply cost

|                            |                |                               |
|----------------------------|----------------|-------------------------------|
| B0 · 100% burn             | 100% burned    | \$0<br>cost 0.25x             |
| B1 · 90% burn / 10% to CCF | 90% burned 10% | \$50k / ticket<br>cost 0.39x  |
| B2 · 80% burn / 20% to CCF | 80% burned 20% | \$100k / ticket<br>cost 0.56x |
| B3 · 70% burn / 30% to CCF | 70% burned 30% | \$150k / ticket<br>cost 0.79x |
| B4 · 50% burn / 50% to CCF | 50% burned 50% | \$250k / ticket<br>cost 1.50x |

## How to read it

**The investor still buys the full ticket on the market.** The dial only changes where the bought tokens go: burned, or delivered to the CCF as treasury reserve.

**Every 10% routed to the CCF** gives the treasury ~\$50k per ticket in QUBIC — and raises our net supply cost, because those tokens are no longer destroyed.

**At 50/50 the cost hits 1.50x** — we create more supply than we destroy. That is the line never to cross.

**The cash variant is the honest one.** Tokens do not pay lawyers or auditors. If the treasury needs funding, take the CCF share as a USDT fee instead (90% market-buy + 10% cash = \$50k hard currency per ticket, same 0.39x cost, ratio lifted to ~1.39 so the investor stays whole).

## Recommendation

B0 for the pilot. Revisit the dial at full scale, when there are real bills to pay.

# The guardrails

## 1 Contract gate

Only a signed investor earns the ratio. Anyone else who burns has simply donated to the burn.

## 2 Attestation gate

The 1.25× is paid only for tokens our market maker attests were bought through the investor's account during the window. Burning an old bag earns nothing.

## 3 No-hedging covenant

No shorts, perpetuals or equivalents for the full release period, backed by a sworn declaration. Breach forfeits every unreleased batch.

## 4 Qubic holds the tokens

Releases come from the programme multisig — 3-of-5 signatories; the custody structure is finalised and published before launch. On breach, releases simply stop.

## 5 Releases too small to dump

Each batch is 0.03%-0.09% of circulating by tier (~40B to ~122.4B), fixed in tokens whatever the price. There is never a block on the market.

## 6 Published before launch

Full terms and addresses public before any investor is approached — tier-1 listing diligence will find an undisclosed allocation, and that discovery is near-disqualifying.

# Why an investor signs

And what we require from them beyond capital.

## What they get

**Up to 20% effective discount without an OTC desk — 10-25% more tokens than their money bought, by tier**

**Smaller cheque, faster money: full repayment in ~6 / ~9 / 12 months by tier**

**No dead period — first batch four weeks after attestation, then every four epochs**

**Full custody — their funds never touch Qubic; the deal is visible on-chain end to end**

***Partnership bonus — Tier C only: +5% (1.25x→1.30x), added to the final batch, funded inside the 24.5% tranche. Lever: give time, not ratio.***

## What we require

### C1 — mandatory for every ticket

Quarterly co-published content, named public support, ecosystem amplification across their channels. No commitment, no allocation.

### Partnership bonus — Tier C, +5%

One verified major deliverable: a confirmed tier-1 listing, a signed live partnership, or a delivered campaign with measurable reach. Paid only on verified delivery, in the final batch; one deliverable credits one ticket.

### Tiers A & B — no bonus

Their advantage is the shorter release. The strategic-partner track requires the strategic-partner cheque — and an anchor with two tickets needs a separate deliverable for each.

# If an investor asks for more discount — the price of yes

The 1.25× (20% effective discount) is the floor and the offer. The dial exists; here is exactly what each notch costs the network.

| Ratio                    | Eff. discount | Our cost / token burned | Net new supply (pilot) | Tranche draw     |
|--------------------------|---------------|-------------------------|------------------------|------------------|
| <b>1.25× — the floor</b> | 20%           | <b>0.25</b>             | 0.64T (0.45%)          | 245B/epoch · 32% |
| <b>1.333×</b>            | 25%           | 0.33 (+33%)             | 0.85T (0.60%)          | 261B/epoch · 34% |
| <b>1.429×</b>            | 30%           | 0.43 (+71%)             | 1.09T (0.77%)          | 280B/epoch · 36% |
| <b>1.667×</b>            | 40%           | <b>0.67 (+167%)</b>     | 1.70T (1.19%)          | 326B/epoch · 42% |

**How to read it:** the curve is convex — every extra 5% of discount costs more than the last. At 30% our cost per burned token is +71% over the floor; at 40% it is +167%, and net new supply nearly triples while the tranche draw climbs past 40% of the weekly burn.

**The negotiating rule stays:** give time, not ratio. Shortening the 12-month schedule costs the network nothing; every notch of ratio is permanent supply. 1.333× is the ceiling, reserved for C3-level strategic value (a tier-1 listing). Beyond it, the model surrenders its advantage over a plain treasury sale.

**The red line: 50% discount (2.0×).** There we issue two tokens for every one burned — the burn story inverts. No ticket is worth crossing it, whatever the name on the term sheet.

# The decision — two paired votes, three design options

## THE COMPUTER QUORUM DECIDES — TWO PAIRED VOTES

Proposal A: redirect 24.5% of earnings from the burn donation (max ~245B/epoch) for a 15-epoch window. Proposal B, published at the same time: restore the full 77.5% burn at the close of epoch 15. No investor is promised anything until both pass.

| Decision                 | Recommendation                     | Why                                                                                                                                                    |
|--------------------------|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| A — Funding window       | 15 epochs (14 nominal + 1 buffer)  | 32% max draw; sized to max liability incl. the Tier C bonus (3.31T vs 3.675T ceiling). Restore vote closes it; all unearned tokens burned.             |
| B — Treasury share       | None for the pilot — 100% burn     | Cleanest story, cheapest supply (0.25×). A cash-fee variant exists for full scale if the quorum wants it.                                              |
| C — Investor obligations | C1 mandatory · Tier C bonus earned | Marketing and partnerships, never a moving purchase ratio. Bonus (+5%, Tier C only) paid in the final batch on verified delivery, forfeited if missed. |

**If no investor signs:** the restore vote closes the window and everything accrued is burned — no tokens issued, nothing lost. Legal and admin setup costs sit outside this decision, requested separately if they arise.

# What is required from each body

The programme team proposes, the core devs build, the quorum decides — in that order. Every item below is in the critical path.

## PROGRAMME TEAM

*proposes and operates*

### Publish the full proposal

Design options (A/B/C), terms, schedule and all addresses public in the qubic/proposal repo before the vote.

### Prepare the legal template

Agreement + attestation format; any costs requested via a separate proposal.

### Operate the programme

3-of-5 multisig signatories appointed and published; releases executed on schedule, on-chain.

### Report publicly

Months 6 and 12: pass/fail against the four pilot tests, published for the quorum.

## CORE DEV TEAM

*scopes and ships*

### No protocol code required

The redirect is a standard donation-split vote — the mechanism that already runs QEarn and the burn.

### Release tooling

Scripted multisig transfers: 13 equal batches per ticket, one every 4 epochs after the cliff.

### Verification tooling

Burn-address monitor + attestation record format, publicly checkable end to end.

### Accrual dashboard

Publish per-epoch accrual vs the 245B ceiling, so actuals are checkable all window long.

## COMPUTER QUORUM

*decides one thing*

### Two paired votes

A: redirect 24.5% of earnings from the burn donation (max ~245B/epoch). B: restore 77.5% at close.

### Everything else untouched

Cap unchanged · miner rewards untouched · QEarn and CCF untouched · restore guaranteed by vote B.

### Sequencing protects everyone

No investor is approached, promised or signed until the vote passes.

### Veto real — before signing

Decline = zero-cost end. Once a ticket is signed, its schedule is honored from accrued tokens; changes touch future tickets only.

# The pilot passes if all four hold

**1** Quorum approves the emission tranche

**2** A real investor signs the full package — attestation, no-hedge, C1 — undiluted

**3** Buy → burn → attest → release completes end to end, on schedule

**4** The marketing and partnership commitments are delivered in the first two quarters

*Fail any one and the full programme does not proceed.*

## Next steps

- 1 Paired proposals published in full (activate + restore) with tier structure settled
- 2 Engineering scopes the release + verification tooling (no protocol code required)
- 3 Counsel drafts the agreement template (costs via separate proposal)
- 4 Both Computer proposals submitted together; programme published in full
- 5 Tickets filled from the tiered investor list — public review at months 6 and 12
